Pre-equilibrium: if the second step were rate-determining. The other possible case would be that the second step is slow and rate-determining, meaning that it is slower than the first step in the reverse direction: $r_2 \ll r_{-1}$. In this hypothesis, $r_1 - r_{-1} \approx 0$, so that the first step is (almost) at equilibrium.

BW = imbinarize(I) creates a binary image from 2-D or 3-D grayscale image I by replacing all values above a globally determined threshold with 1s and setting all other values to 0s. By default, imbinarize uses Otsu's method, which chooses the threshold value to minimize the intraclass variance of the thresholded black and white pixels .
