R uses lexical scoping 37: it looks up the values of names based on how a function is defined, not how it is called. "Lexical" here is not the English adjective that means relating to words or a vocabulary. It's a technical CS term that tells us that the scoping rules use a parse-time, rather than a run-time structure.

The rule-based deterministic lemmatizer maps the surface form to a lemma in light of the previously assigned coarse-grained part-of-speech and morphological information, without consulting the context of the token. The rule-based lemmatizer also accepts list-based exception files. For English, these are acquired from WordNet.

Chunks, then, can be mapped as a semantic network, given that each node is a chunk with its unique properties, and each link is the chunk's relationship to another chunk. In ACT, a chunk's activation decreases as a function of the time since the chunk was created and increases with the number of times the chunk has been retrieved from memory.

Modules have a lexical top-level scope. This means that for example, running `var foo = 42;` within a module does not create a global variable named `foo`, accessible through `window.foo` in a browser, although that would be the case in a classic script. Similarly, the `this` within modules does not refer to the global `this`, and instead is undefined.
